## **Bayesian Ridge Regression**

Computes a Bayesian Ridge Regression on a synthetic dataset.

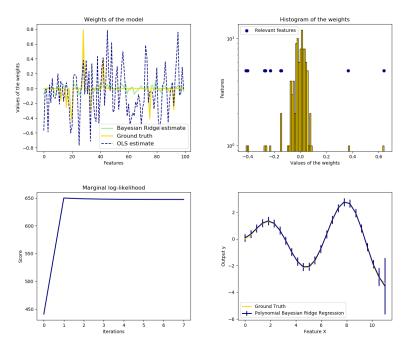

See Bayesian Ridge Regression for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

As the prior on the weights is a Gaussian prior, the histogram of the estimated weights is Gaussian.

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for Bayesian Ridge Regression for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

print(\_\_doc\_\_) import numpy as np import matplotlib.pyplot as plt from scipy import stats from sklearn.linear\_model import <a href="mailto:BayesianRidge">BayesianRidge</a>, <a href="mailto:LinearRegression">LinearRegression</a> # Generating simulated data with Gaussian weights np.random.seed(0) n\_samples, n\_features = 100, 100 X = <u>np.random.randn(</u>n\_samples, n\_features) # Create Gaussian data # Create weights with a precision lambda\_ of 4.
